Artificial Intelligence**

Your Name

Submitted on: November 24, 2025

Supervisor: Prof. Dr. Magda Gregorova
Second Examiner: Prof. Dr. C D

Abstract (en)

A single paragraph summarizing the most important points of your thesis. This can be more than one paragraph but should not be too long. You usually write this as the very last thing of your thesis.

Abstract (de)

We are in germany so include a translation.

Acknowledgment

Here you can thank your friends who helped you throughout the studies, your parents for supporting you generally, if you wish your supervisor or any other profs and generally everybody you value.

1 Introduction

1.1 Motivation

Scalable Vector Graphics (SVG) play an essential role in modern digital design due to their scalability, compactness, and support for semantic editing. Unlike raster images, SVGs describe visual content through structured, text-based geometry using paths, shapes, and hierarchical groupings, allowing for precise control, reusability, and easy modification.

In recent years, machine learning and deep learning models have been applied to the generation of SVGs from various input modalities, such as text prompts, raster images, and sketches. Open-source research has produced a variety of approaches, including sequence models, transformer-based architectures, and differentiable optimization methods, each proposing different strategies for representing and producing vector graphics.

Given this diversity, it becomes relevant to study how these open-source models differ in their architectures, internal representations, and the structure of the SVGs they generate. Understanding these aspects can provide a clearer picture of how SVGs are represented and produced computationally, and what factors may influence the quality and editability of the resulting graphics.

1.2 Problem Statement

While multiple open-source models exist for SVG generation, they employ heterogeneous approaches in terms of architecture, data representation, and output structure. Some models treat SVGs as sequences of drawing commands, others as hierarchical objects, and still others as continuous geometric parameters optimized through differentiable rendering.

This diversity makes it challenging to compare how different approaches handle SVG generation and how these choices influence the final output. Furthermore, the evaluation

of SVG quality often depends on various factors, such as path simplicity, structural organization, and editability, which are not always measured in the same way.

Therefore, the problem addressed in this research is to systematically describe, compare, and analyze open-source SVG generation methods, focusing on their architectures, internal representations, and output characteristics, in order to understand how these design choices relate to the quality and structure of the generated SVGs.

1.3 Research Goals

1. To explain and analyze the core properties, structures, and components of SVG graphics as a foundation for understanding their representation and generation.
2. To collect, review, and categorize existing open-source methods for SVG generation across various input modalities.
3. To investigate the types of deep learning and machine learning architectures employed in SVG generation models and analyze their design principles.
4. To examine how these architectures represent SVG data internally and how their outputs are transformed into standard SVG files.
5. To explore and evaluate existing approaches, metrics, and benchmarks for assessing the quality of generated SVGs.
6. To assess and compare the output quality of current SVG generation models based on the identified evaluation criteria.

1.4 Research Questions

1. What are the main properties and structures that define an editable and high-quality SVG?
2. What open-source methods currently exist for generating SVGs from different input modalities?
3. What types of deep learning and machine learning architectures are models used for SVG generation?

4. What kinds of structure do these models produce?
5. How can the quality and editability of generated SVG be evaluated?
6. What is the observed quality of SVG outputs across different models?
7. What makes open source model suitable for testing?
8. Which open-source SVG generation models are most suitable for testing and comparison?
9. How do the selected open-source SVG generation models perform in terms of defined criteria (eg. editability, quality and practical usage)?

2 Systematic Literature Review

Kitchenham’s guidelines were originally developed for evidence-based software engineering and have become one of the most widely adopted standards for conducting systematic literature reviews in computer science and technical research disciplines [1]. The methodology provides detailed, domain-specific procedures for planning, searching, selecting, and synthesizing studies in areas where research outputs are often heterogeneous—such as algorithmic models, machine learning architectures, or engineering pipelines. Unlike biomedical-focused protocols such as PRISMA [2], which were designed primarily for clinical trials and human-subject research with standardized quantitative outcomes, Kitchenham explicitly addresses challenges unique to computational research: diversity of study designs, inconsistent terminology, non-uniform evaluation metrics, and the frequent presence of code-based or algorithmic artifacts instead of comparable statistical datasets. Similarly, frameworks like SALSA [3] emphasize high-level structuring but do not prescribe the step-by-step operational procedures needed for reproducibility in technical fields.

For this thesis—situated within deep learning, machine learning, and vector-graphics generation—a Kitchenham-style SLR is needed because the literature consists of diverse model architectures, varied input modalities, and different evaluation criteria. Kitchenham’s protocol supports this complexity by providing structured phases (planning, conducting, and reporting) that guide the reviewer through formulating rigorous research questions, defining search strategies, operationalizing selection criteria, assessing methodological quality, and performing narrative synthesis. This structure minimizes bias, increases reproducibility, and ensures that the review captures the full range of relevant deep-learning and vectorization approaches. Consequently, Kitchenham offers the most appropriate methodological foundation for achieving a systematic, transparent, and technically robust synthesis of current research on SVG-related generative models [4].

Study Selection Criteria

Inclusion Criteria:

- **Language and Publication:** Written in English and published in a peer-reviewed journal, conference, or workshop.
- **Time Range:** Published between 2020–2025 (post-emergence of modern SVG generative models such as DeepSVG).
- **Domain Relevance:** Falls within computer vision, computer graphics, AI, machine learning, or deep learning.
- **Reproducibility:** Provides an open-source implementation or references a publicly available repository. Availability of pre-trained weights is preferred, but source code alone is sufficient if the method is reproducible.
- **SVG Output Requirement:** Describes a model, method, or architecture that directly generates SVG or structured vector outputs, including:

- Bézier curves,
 - SVG `<path>` commands,
 - layered or hierarchical SVG structure,
 - vector strokes or SVG-like stroke sequences,
 - structured outputs suitable for editability analysis.
- **Input Modalities:** Supports at least one of:
 - image-to-SVG vectorization,
 - text-to-SVG generation,
 - multimodal SVG generation,
 - **Architectural Transparency:** Provides sufficient technical detail to extract the model architecture or internal SVG representation (e.g., decoder design, transformer layers, vector tokenization, differentiable rasterization, or geometric parameterization).
 - **Evaluation:** Provides quantitative metrics and/or qualitative SVG examples that allow analysis of structural quality and editability.

Exclusion Criteria:

- **No Vector Output:** The method does not generate vector or SVG outputs (pixel-only image generation).
- **Non-ML Methods:** Purely rule-based or classical algorithmic vectorization methods without machine learning or deep learning.
- **Closed-Source Systems:** No publicly available code, weights, or sufficient technical detail for reproduction.
- **Insufficient Evaluation:** Papers lacking SVG evaluation, qualitative vector examples, or any structural analysis of outputs.
- **Out-of-Scope Vector Work:** Studies focused solely on vector editing, rendering,

compression, markup optimization, or stylistic modification without SVG generation.

- **Domain Mismatch:**

- handwriting synthesis,
- font generation,
- datasets,
- sketch generation not intended for SVG graphics.

- **Temporal Exclusion:** Studies published before 2020, except when cited for historical context only.

- **LLM Restriction:** Proprietary LLMs (e.g., GPT-4, Gemini, Claude) that can emit SVG text but do not provide open-source architecture, reproducible training details, or transparent vector representations.

Study Selection Procedure

- Initial records
- Duplicate removal
- Title/abstract screening
- Full-text assessment
- Final included studies

Quality Assessment Criteria Based on Kitchenham:

- Clear aims and objectives
- Clear description of methodology
- Clear model/method architecture
- Appropriate study design

- Evaluation methodology
- Clear results
- Discussion of limitations
- Open-source implementation

Data Extraction Plan

- Bibliographic metadata
- Study context and goals
- Model/method characteristics
- Vector structure and SVG properties
- Evaluation metrics and results
- Reproducibility details

2.2 Phase 2 — Conducting the Review

2.2.1 Execution of the Search Strategy

The search strings defined in Phase 1 were executed across the selected databases (Google Scholar, arXiv, and ACM Digital Library) to identify relevant literature on SVG generation and vector-based deep learning methods. Searches were performed using the conceptual string groups defined in the search strategy, with database-specific syntax adjustments where necessary. All records retrieved by these searches were exported and documented before any filtering or removal of duplicates. Table 2.1 summarises the number of studies returned by each search group and database.

Table 2.1: Search Log Summary Across Databases and Conceptual Groups

Search Group	Google Scholar	arXiv	ACM DL	Total
SVG Generation	18	15	4	37
Raster-to-Vector	10	8	2	20
Text-to-SVG / Multimodal	7	10	5	22
Surveys/Benchmarks/Reviews	6	3	1	10
SVG Fundamentals / Background	3	3	2	8
Total Hits	44	39	12	95

2.2.2 Removing of Duplications

After merging all search results, duplicate records—including repeated titles and preprint–conference duplicates—were removed. This resulted in 72 unique studies.

2.2.3 5. Study Selection

- Stage 1: Title, Keywords and Abstract screening.

After removing duplicates, **72** unique studies remained. A brief title and abstract screening excluded works clearly unrelated to SVG generation (e.g., sketch-only models, raster methods, classical vectorization, or closed-source LLMs), resulting in **38** papers proceeding to full-text review.

- Stage 2: Full-text screening

2.2.4 6. Study Quality Assessment

Apply the quality checklist.

2.2.5 7. Data Extraction

Use standardized extraction tables.

2.2.6 8. Data Synthesis

8.1 Narrative Synthesis Summarize findings, patterns, and categories.

8.2 Sensitivity Analysis Remove low-quality studies and reassess.

2.3 Phase 3 — Reporting

2.3.1 9. Prepare the SLR Report

Document all methodology, results, synthesis, and identified gaps.
